WHITE PAPER

New Locations and New Requirements for Onboard IP CCTV

Harry Hsiao

Product Manager

MOXA®

Overview

IP-based CCTV systems are becoming an absolute requirement for train operations. Effective video surveillance protects passenger safety and makes train operations more efficient, which has led to increased investment in onboard IP CCTV systems. These systems have expanded in scope and reach, and cameras are now being deployed in more and more locations throughout the train. These new video surveillance applications have introduced important new IP video requirements: as IP cameras are deployed in more and more locations onboard a train, there is a corresponding increase in the performance, reliability, and design requirements for those IP cameras.

Advanced IP CCTVs Deliver Operational Efficiency

The conventional use case for CCTV systems has been to provide security. However, in intelligent railway systems, operators have found that CCTV systems can also make operations more efficient by providing key visibility and live information. With an advanced and integrated IP CCTV system, train operators can get an immediate live view of the status inside or outside the train at specific key locations. The train operator, whether onboard or in a control room, can use this information when loading and unloading passengers, checking the status of the routes, or identifying when a train car is full.

More Deployment Locations Needed

Train operators can only truly realize the operational benefits of IP CCTV systems if the system is sufficiently advanced, and camera coverage is sufficiently thorough. Whereas in the past, it was sufficient just to install a few consist cameras with broad surveillance coverage of the carriage, modern systems give operators greater situational awareness by making video surveillance more pervasive. This means more cameras, in more locations, doing more work. For example, consider the tram project illustrated on the following page.

Released on April 3, 2013

Moxa manufactures one of the world's leading brands of device networking solutions. Products include industrial embedded computers, industrial Ethernet switches, serial device servers, multiport serial boards, embedded device servers, and remote I/O solutions. Our products are key components of many networking applications, including industrial automation, manufacturing, POS, and medical treatment facilities.

This tram contains multiple cameras, installed throughout the train:

1. Forward and rear facing cameras (Zones 1 and 2). These two cameras monitor the track status, and work with the event data recorder in the train car.
2. Retro-vision cameras (Zones 3 to 6): These cameras are mainly for the driver or operator to view the passengers entering and exiting the train when it is stopped at the platform, or to record the trackside situation when the train is moving.
3. Car control cameras (Zones 7 and 8). These cameras are located in the driver's cabin, or in an unmanned train, the control room. They monitor the status of the train control panel and LED signals.
4. Pantograph camera (Zone 9). For trains that use overhead wiring, this exterior, roof-mounted camera monitors the pantograph that connects the train or tram with the catenary overhead line.
5. Door cameras (Zones 10 to 13, 16 to 19). These cameras monitor passengers entering or exiting through each specific door. This interior view supplements the driver's exterior view of the doors via rear-view cameras. In addition, this video recording can be used for reviewing ticketing information, as some systems may use video-based person-counting technology.
6. Consist cameras (Zone 14, 15, 20). These cameras monitor the situation inside the car. illustrated below.

While just these six location types will bring the number of cameras in a consist to about 15, there are even more new camera deployment locations that are growing common in modern systems.

7. Intercom cameras. Most trains will include an intercom system for emergency communications between passengers and the driver or operations control center. Intercom activity is recorded and logged for later review. One modern innovation is to add a camera to the intercom system, so the driver or operator can see who is speaking into the intercom. Like audio, the video is also recorded for later review.
8. Zone-specific cameras. Additional video coverage can be useful at certain critical locations on the train, such as priority seats, vending machines, luggage areas, the bike parking area, machine cabinets, etc. Dedicated cameras devoted to these locations can provide added security

New Requirements for Onboard IP CCTV Cameras

These new camera deployment locations have directly contributed to another trend: growing camera performance requirements. On-board cameras must meet many demanding requirements.

More Form Factors: Now that IP cameras are deployed in more locations, more form factors are needed to match. When the CCTV system is simply covering a broad, general area, just common dome or box-type cameras are enough. Now that IP cameras are being deployed in more locations, the requirements are specific. For example, rear-view and pantograph cameras are mounted on the train exterior and need a rugged form factor that can be both aesthetically pleasing to the eye and able to operate consistently in harsh conditions. Inside the train, the intercom camera must be discreet enough to tuck into the intercom system, hidden inside the wall.

Day and Night View: On-board IP cameras are usually designed only for daytime viewing, as they are designed with the expectation that there will be interior lighting in train cars. However, cameras providing trackside viewing need both day and night view capability in order to handle low illumination conditions at night. In addition, some trains use low lighting in the driver or control rooms. Cameras in these conditions will also need nighttime viewing capability.

High Video Performance: Trackside cameras must record in high resolution and at high frame rates in order to capture meaningful video while the train is moving quickly. Otherwise, the video will just be a blur. Typical requirements for on-board IP cameras are 10 to 15 frames per second, and 640x480 or 720x480 resolution. In contrast, trackside cameras need much higher performance, of around 30 frames per second and 1280x720 resolution.

Extreme Operating Temperature: Trains both inside and outside the carriage are now asked to operate consistently in extreme temperatures. This is because more and more train operators expect to be able to monitor onboard conditions at any time, even when the air conditioning is inactive while the train is on standby in the garage. Therefore, cameras need to be able to meet the EN 50155 T3 (-25 to +70°C) or TX (-40 to +70°C) temperature criteria.

High EMI/ Surge Protection Level:EMI and surge protection are another new requirement that have been introduced by new IP camera deployments. Usually, the on-board CCTV cameras are installed in a safe environment where EMI and surge protection is not very important. Cameras mounted on the train exterior are another story. For these cameras, it is important to possess EMI and surge protection to ensure consistent system performance. The minimum requirement in this category is defined by the level 3 criteria in the EN 50121-3-2 (IEC 62232-3-2) “Railway Applications – Electromagnetic Compatibility” standard for rolling stock.

Moxa’s Comprehensive EN 50155 Rolling Stock IP CCTV Solutions

Moxa's comprehensive IP CCTV solution includes network switches, wireless communications, IP video products, video management software, and NVR platforms for rolling stock applications.

Moxa's portfolio includes a solution for every application and every installation environment. Moxa provides three different types of EN 50155 IP cameras, which can be deployed as consist IP cameras, rear-view IP cameras, and also flush-mounted as hidden IP cameras. All three are rugged and come with M12 Ethernet connectors, PoE power input, and compliance with key EN 50155 and EN 50121-3-2 criteria. In addition, video resolution up to 1280x800 in H.264 and MJPEG are both available for live viewing or video recording.

In addition, for applications that need to operate in extreme temperatures, cameras are available with an optional -40 to 75°C operating temperature. These cameras are the first in the world to be compliant with the higher EN 50155 TX criteria. Moxa's cameras do not use built-in heaters or fans, which eliminates a potential point of failure and delivers excellent product longevity of 10 to 20 years in railway applications.

A diverse selection of form factors makes it possible to deploy IP cameras in more locations

In addition to IP cameras, Moxa provides EN 50155 M12 Ethernet switches, EN 50155 NVR platforms, EN 50155 wireless APs, and NVR software. All these products combine to build a complete EN 50155 IP CCTV system. To simplify configuration, all EN 50155 products are equipped with Moxa FLI™ configuration technology, which automates network setting and device configuration.

Moxa's broad selection of EN 50155 products
